The TherAdapt Early Intervention Prone Stander is designed to safely and appropriately support a child in a weight bearing position that best suits their individual standing abilities and support needs. The unique knee and trunk components permit the child to be at eye level with peers, for maximum benefit of social interaction and academic participation. The TherAdapt Prone Stander is recommended for children who require anterior support, display emerging head and trunk control, or are beginning to right themselves from a prone position. The stander adjusts in height from 20" to 28", and will safely and effectively support a small child up to preschool age.

Please be sure to seek the guidance of a physical therapist or occupational therapist for proper positioning and safety when using this piece of equipment.
